## INTRODUCTION AND OBJECTIVES

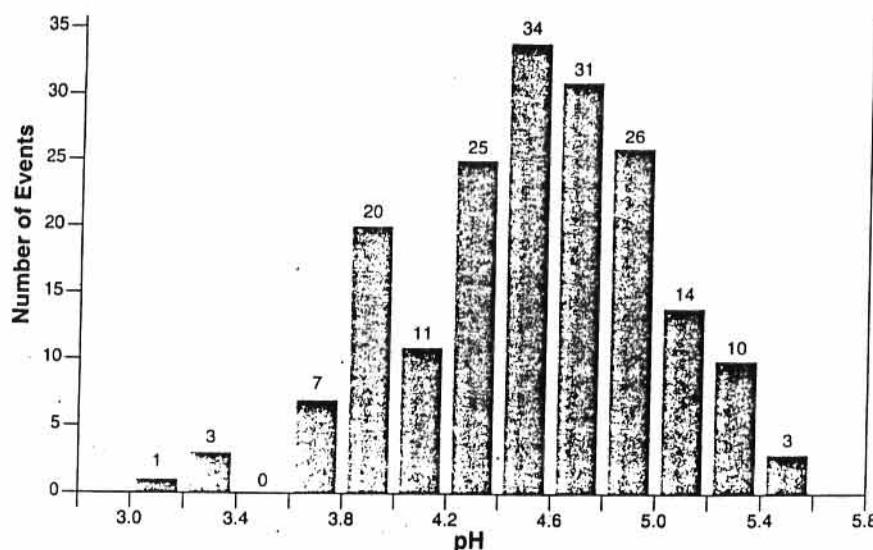

Kejimkujik National Park, located in southern Nova Scotia (Fig. 1), represents the Atlantic Coast Uplands Natural Region ecosystem.

**Fig. 1 Kejimkujik National Park, N.S.**

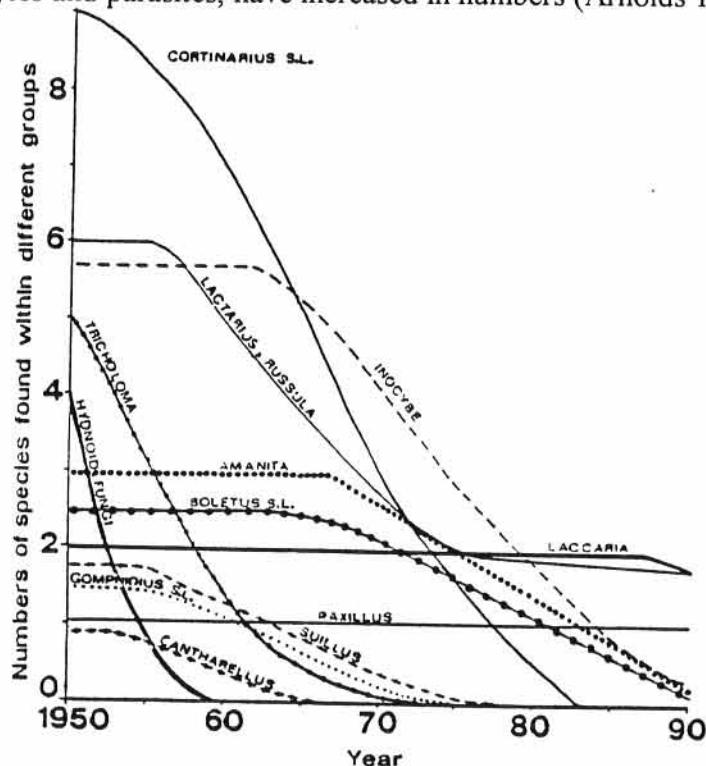

It consists of low-rolling hills, lakes, streams, and forests. During 1990 - 1991 five permanent plots were established in Kejimkujik National Park, representing the diverse forest ecosystems of the Park. The plots were designed to study long-term effects of air pollution on fleshy basidiomycete fungi (Polach 1992). Similar studies in Europe over the past two decades have revealed that some fungi can be excellent bioindicators of forest ecosystem health ( Fellner 1989; Arnolds 1991, 1992). The bioindicator fungi belong to ectomycorrhizae - a group of terrestrial basidiomycete fungi that grow in mutualistic symbiosis with the roots of higher plants, especially forest trees, and are one of major components of the temperate forest ecosystem.

Due to the long-range transport of air pollutants from industrial areas of Eastern North America the Park has been receiving high amounts of significantly acidic precipitation for a number of years (Fig. 2, Tab. 1). The effects of the acidity on the Park's ecosystems have been documented in a variety of studies (Drysdale 1995, pers.comm.).

**Fig. 2 Distribution of pH in precipitation events in Kejimkujik, N.S., 1992 (Beattie and Hanley 1989)**

As mentioned above, some fungi appear to be good bioindicators of changing acidity levels in the ecosystem. In parts of Europe, where the air pollution levels are high, it has been observed that many ectomycorrhizal taxa have experienced a significant decline in species diversity over past few decades (Fig. 3), while some other fungal taxa, especially the wood-inhabiting saprophytes and parasites, have increased in numbers (Arnolds 1991).

**Fig. 3 Changes in the numbers of different species of ectomycorrhizal fungi between 1950 and 1990 in some areas in Netherlands (in Arnolds 1991, reproduced by permission)**

As it has been proposed by some researchers, monitoring populations of terrestrial fungi can help in assessing the forest ecosystem health and its possible decline in the future (Fellner 1990).

After establishing a baseline for the five permanent plots during 1990-1991, a second survey attempts to re-examine two of the plots in 1995, and document and discuss any possible changes in the species composition.

In April 1994 two new permanent plots were established in the Park. The plots were set up using the methodology developed by the Smithsonian Institution in Washington, D.C., as a part of the Smithsonian Institution/Man and Biosphere Biological Diversity Program - SI/MAB (Dallmeier 1992). Smithsonian plots attempt to standardize methods for studying forest biodiversity and are now being developed in many areas worldwide. Their main objective is to study biodiversity of different forest ecosystems and to look for possible links among components by using multidisciplinary approach.

A survey of terrestrial fungi will be conducted in the Smithsonian plots in the Park creating a baseline for future research in the area of fungal ecology.

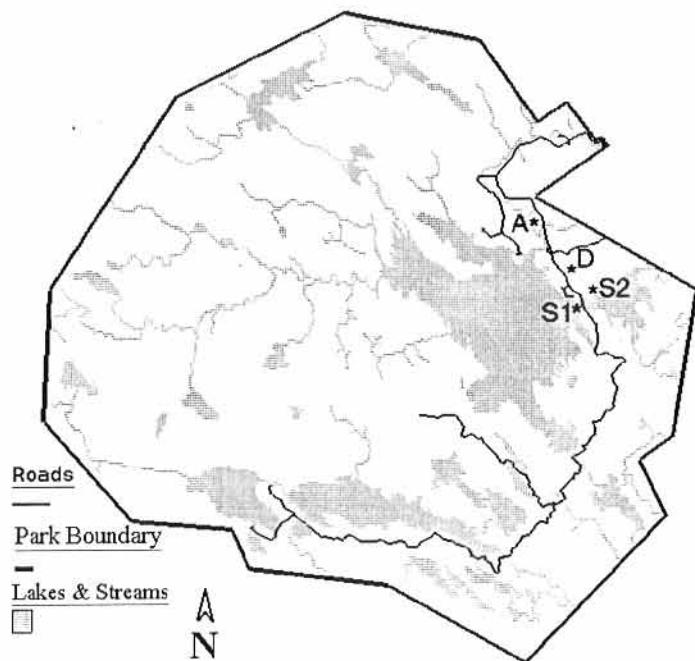

#### Objectives:

1. To re-survey two of the five plots established between 1990-1991 and discuss possible changes in the species diversity
2. To survey fleshy terrestrial basidiomycete fungi in selected areas of two Smithsonian plots and create baseline data for future studies
3. To develop a computer database of the results

## **PLOT DESCRIPTION AND METHODOLOGY**

#### Plot location

Four permanent plots were surveyed in 1995. The general location of the plots within the Park is shown in Figure 4.

**Fig. 4 Location of plots surveyed in 1995**

Plot A: Located near the forest edge, about 150 meters before turnoff to Rodger's Brook on the right side of the main parkroad, perpendicular to the main parkroad.

Plot D: Located approx. 200 meters south of the Ferry Bay Look Off Tower on the left side of the main parkroad. Take a true bearing of 92 degrees from a metal stake placed near the forest edge for 152 meters.

SI/MAB Plot I: Located approx. 150 meters southwest of the Grafton Brook Bridge (right/west side of the dirt road). (Easting 324350 Northing 4916350) NAD27

SI/MAB Plot II: Located approx. 200 meters east of the eastern end of the Grafton Lake interpretation trail and 75 meters north of the north shore of Grafton Lake. (Easting 325250 Northing 4917100) NAD27

#### Plot description

Plot A: Plot is a 30x30 meters coniferous forest stand with *Pinus strobus* (White Pine), *Tsuga canadensis* (Eastern Hemlock), *Abies balsamea* (Balsam Fir), and *Picea glauca* (White Spruce) as dominant species. Few areas of the plot are covered with mosses.

Plot D: Plot is a 30x30 meters deciduous forest stand with *Acer saccharum* (Sugar Maple), *Acer rubrum* (Red Maple), and *Fagus grandifolia* (Beech) as dominant species. Other tree species present are *Betula papyrifera* (White Birch), *Quercus rubra* (Red Oak), and *Acer pensylvanicum* (Striped Maple). Grasses and mosses are present in some areas of the plot.

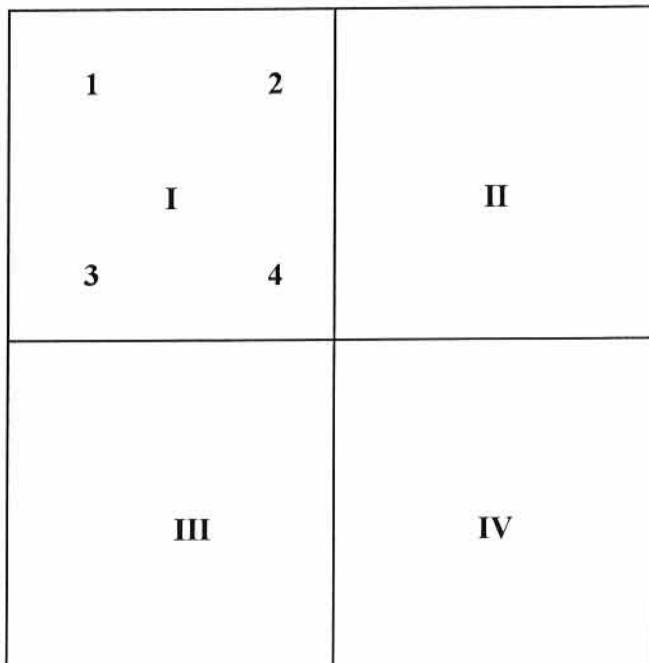

SI/MAB Plot I: Plot is a 1 hectare stand dominated by hardwood species with some white pine. Detailed tree data for sampled quadrats are available from a separate study and are included in the Appendix 16. (Slides are also included).

SI/MAB Plot II: Plot is a 1 hectare stand dominated by coniferous species with some red maple. Detailed tree data are available from a separate study and are included in Appendix 17. (Slides are also included).

#### Methodology of plot establishment:

##### Plots A and D establishment:

Each plot is a 30x30 meter square so that the total area is 900 m<sup>2</sup>. The plots were set up with a compass and a standardized 30 meter rope. Corners and centre of each plot were made visible with permanent aluminium poles. Each plot was further subdivided into additional 15x15 meter quadrats with a set of temporary strings. The four 15x15 meter quadrats were assigned Roman numerals (Fig. 5).

**Fig. 5 Plot quadrats layout**

Specimens found in the plot were located by using the above grid system, with additional subquadrats created in each Roman quadrat to determine a more precise area for each specimen.

Plots SI/MAB I and II:

Plots were set up using the methodology described in Dallmeier 1992. Both plots are one hectare in size and are subdivided into 25 quadrats of 20x20 meters each. Three 20x20 meter quadrats were selected in each plot for collecting the fungi (Fig. 6-7).

### Collecting

Collected specimens were wrapped in wax paper and transported to a laboratory to be determined using available literature (Bird 1979; Dahncke 1979; Grund 1976; Hadjisterkoti 1938; Halling 1983; Hesler 1979; Largent 1988; Lincoff 1981; McAfee 1982; Moser 1978; Phillip 1981,

1991; Smith 1947, 1964). Upon drying, specimens were placed in labelled envelopes and deposited in the Acadia University mycological collection with assigned ACAD numbers (Polach 1992). During 1990-1991, all specimens found were assigned the ACAD number. In 1995, only first specimen of each species found was collected and assigned the ACAD number; any subsequently found specimens of the same species were not collected, although they are included in the database without a number.

It is important to stress that collecting mushrooms is non-destructive (ie. only fruit is removed from the substrate). Nevertheless, only the number of mushrooms necessary for identification and/or for a herbarium collection is removed from the sites.

Collecting commenced the week of July 17-23 in SI/MAB plot I and II, and the week of July 22-30 in plots A and D. Collections were made as frequently as possible, ie. once a week. Upon identification of collected specimens, the data were entered into a master Dbase file with the following information: ACAD number, species, location, date, and type (Mycorrhizal or Other) (see Appendices). Since there existed no computer database for the data from 1990 - 1991 survey, the data were processed in the same manner. From the master file several other files were sorted out for each of the four plots using the following criteria:

1. Date of collection
2. ACAD number
3. List of species

Precipitation data, which may play an important role in analysis of fungal occurrences and growth patterns, come from Park's sources and are included in the Appendix 15. Some additional data include: temperature fluctuations during collecting periods (Figure 8), yearly data on precipitation pH and hydrogen ion wet deposition (Tab. 1), soil pH data in SI/MAB plots (Fig. 11), and a complete tree analysis of surveyed quadrats in the SI/MAB plots (Appendices 16-17).

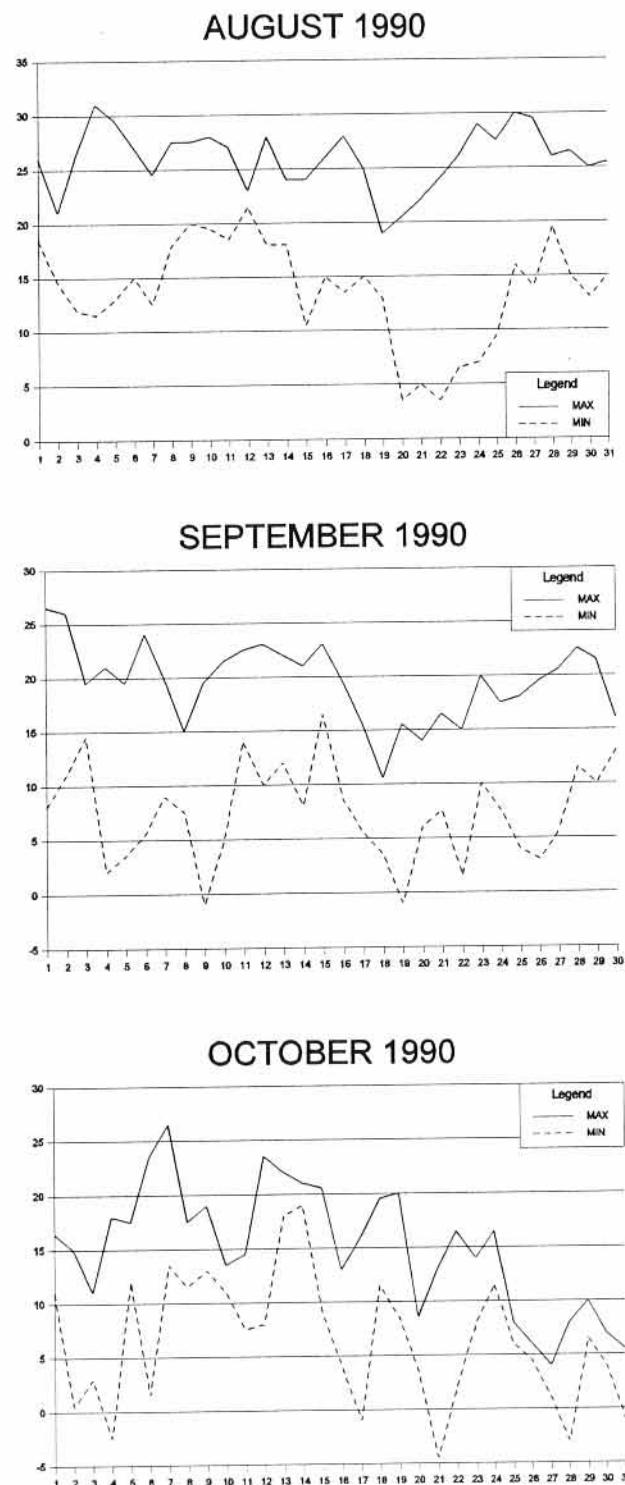

## RESULTS AND DISCUSSION

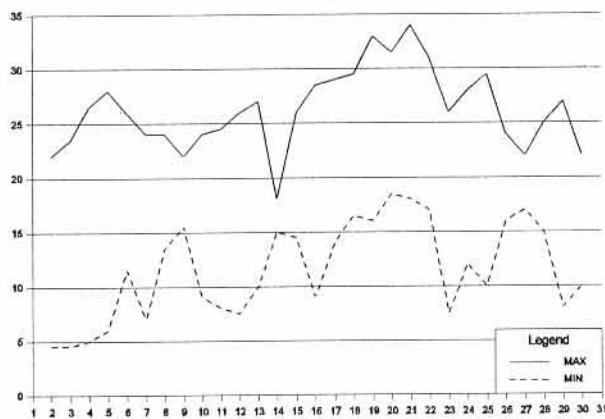

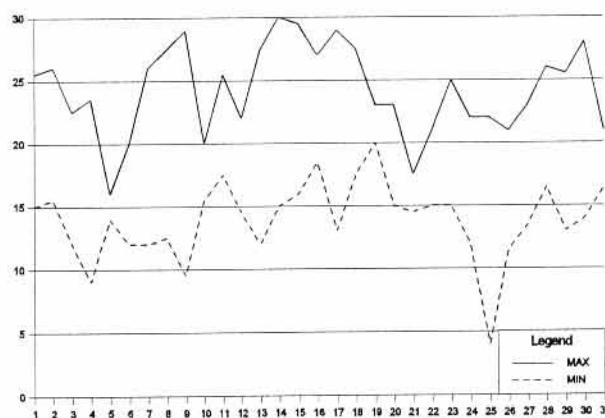

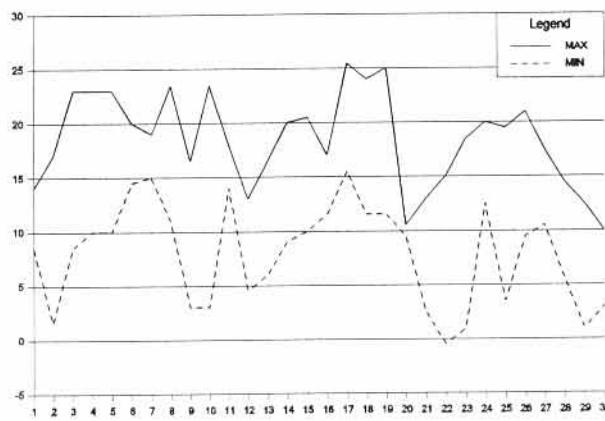

Data on precipitation pH and temperature fluctuations are presented in Table 1 and Figure 8, respectively.

	1990	1991	1992	1993	1994
PREC (mm)	1610	1440	1180	1480	1650
H <sup>+</sup>	0.38	0.38	0.32	0.32	0.33

## **Biomonitoring - plots A and D**

### **Species data for 1991 and 1995**

Fungi were collected in plots A and D during 1990-91 and 1995 collecting seasons. However, the collecting in 1990 commenced later in the season and this is one of two reasons why its results are not included in the analysis. The other reason is that in order to collect significant data on macrofungi in temperate forest ecosystems, collecting should be done for at least 2 - 3 consecutive seasons (Fellner 1995, pers. comm.). The 1995 data that are being compared to the 1990-91 baseline study come from only a single collecting season, therefore they are being compared to the data from 1991. This is clearly a compromise, because there is a variety of environmental factors that could affect fungal fruiting in a single season. It is important to remember that although some fruiting bodies (mushrooms) may not be found due to the environmental factors in one season, the species may still be present in its vegetative form and fruit next year or when the environmental factors are favourable. While there are some fungi that fruit only once every 10-20 years, 2-3 years are usually sufficient for gathering significant data on macrofungi in temperate forests, since the majority of the species present is likely to fruit during this time period.

The data collected in plots A and D during 1990-91 seasons have been entered into a Dbase file and sorted by collection date (Appendices 1 and 6), and by the ACAD number (Appendices 2 and 7). The alphabetical lists of all collected species for both plots during 1990-91 are also included (Appendices 3 and 8). The alphabetical lists of species found during the 1991 season in the plots A and D can be found below (Tabs. 2 and 4, respectively). The data from plots A and D in 1995 have also been entered into a Dbase file and sorted in the same fashion (Appendices 4,5,9 and 10). The alphabetical lists of species found during 1995 in the plots A and D have been included below (Tabs. 3 and 5, respectively).

**Tab. 7** Number of all species (mycorrhizal in parentheses) found during collecting periods in Plot D

YEAR	SPECIES
1990	40 (19)
1991	90 (58)
1990-91	111 (68)
1995	62 (26)

As mentioned earlier, the potential for a complete and significant analysis of the data is rather low at this point. There appears to be a decline in the total number of species in both plots from 1991 to 1995 - from 51 to 41 in the plot A (Tab. 4), and from 90 to 62 in the plot D (Tab. 7). The decline in the numbers of mycorrhizal species seems to be even higher - from 42 to 24 in the plot A (Tab. 4), and from 58 to 26 in the plot D (Tab. 7). However, it is important to realize that there is a significant difference in the precipitation amounts between the two seasons (Appendix 15). The difference has been summarized in Table 8. The data indicate that the amount of precipitation during the researched period in 1995 was over 50% lower than in 1991. Moreover, the month of September, when a majority of macrofungi fruit in Kejimkujik, was affected by the lack of precipitation the most (Appendix 15).

**Tab. 8 Summary of precipitation data (in mm) between July 1 and October 15 during 1991 and 1995 and percentual change**

	1991	1995
$\Sigma$	462.6	209.6
%	100	45.3

The only comparison between the two collecting seasons that seems appropriate under these circumstances is the percentual contribution of mycorrhizal species to the total number of species in the individual plots, since both - mycorrhizal and non-mycorrhizal groups - are expected to have been affected by the lack of precipitation equally (Tabs. 9-10).

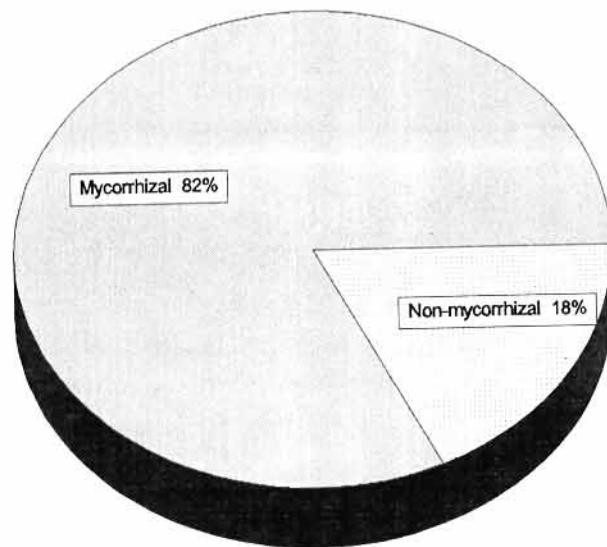

**Tab. 9 Percentual contribution of mycorrhizal species (M) to total number of species in 1991 and 1995 in Plot A**

	TOTAL SPECIES	M	%
1991	51	42	82
1995	41	24	59

**Tab. 10 Percentual contribution of non-mycorrhizal (N-M) to total number of species in 1991 and 1995 in Plot A**

	TOTAL SPECIES	N-M	%
1991	51	9	18
1995	41	17	41

Tab. 12

**Percentual contribution of non-mycorrhizal (N-M) species to total number of species in 1991 and 1995 in Plot D**

	TOTAL SPECIES	N-M	%
1991	90	32	36
1995	62	36	58

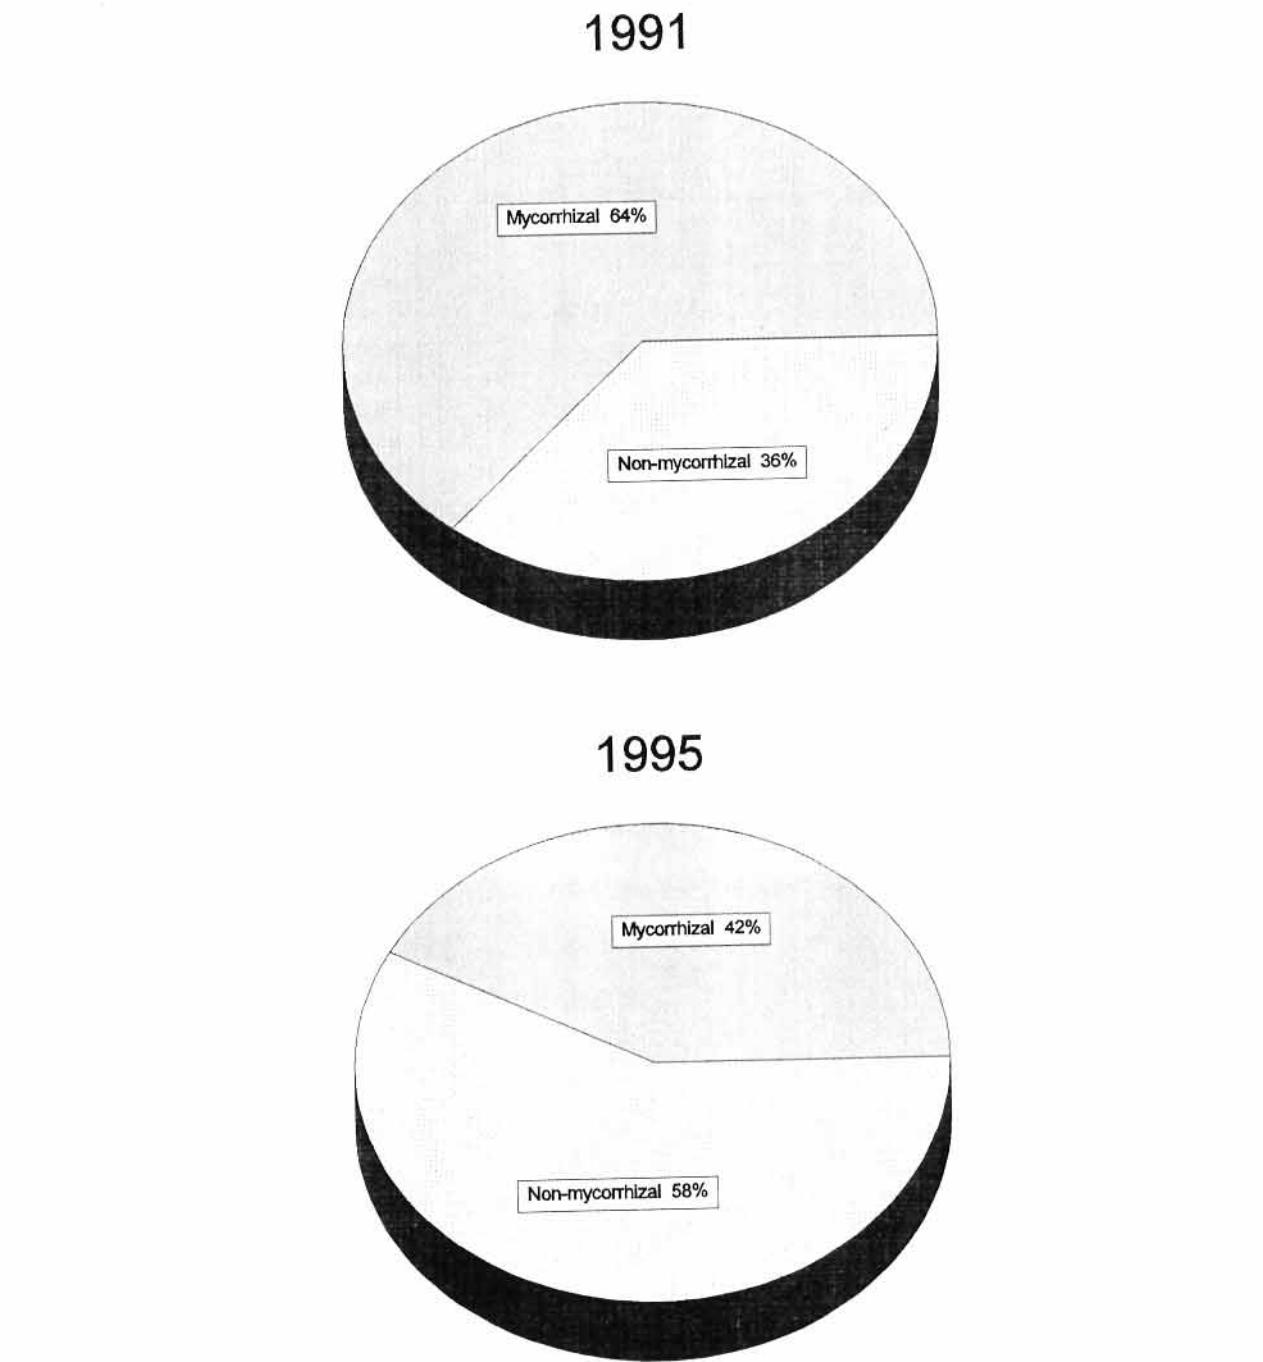

Fig. 10      Graphs of mycorrhizal and non-mycorrhizal contribution to total number of species in 1991 and 1995 in Plot D

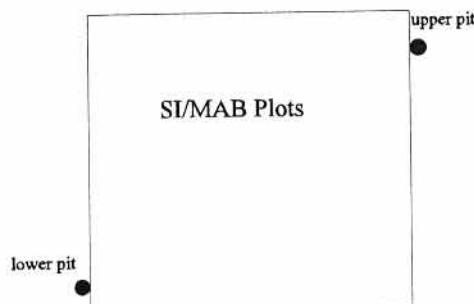

The data from both plots indicate a substantial shift in the contribution of mycorrhizal and non-mycorrhizal species to the total number of species between 1991 and 1995, with a declining contribution of the mycorrhizal species. In both plots, the degree of the decline appears to be similar - the mycorrhizal contribution has decreased by 23% in Plot A and by 22% in Plot D.

Whether the results indicate a long-term trend, known from some European countries, where mycorrhizal fungi have been on a steady decline, or are only a short-term fluctuations remains to be seen. The study needs to be continued and the sampled areas re-surveyed at regular intervals with a 2-3 years span. Only in this way a complete analysis of the obtained data can be provided.

### SI/MAB Plots

Soil pH data for SI/MAB plots I and II are included in Figure 11.

**Fig. 11      Soil pH data for SI/MAB Plots I and II (Arp 1995)**

**Baseline species data for SI/MAB Plots I and II for 1995**

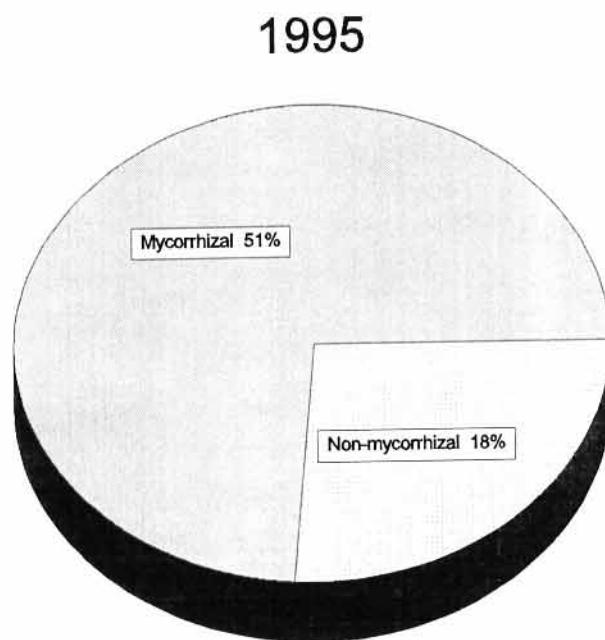

SI/MAB Plots I and II were collected once every week between July 19, 1995 and October 12, 1995. The data have been entered into a Dbase file and sorted by collection date and ACAD number (Appendices 11-14). In total, 51 species (18 mycorrhizal) were found in Plot I, and 82 species (32 mycorrhizal) were found in Plot II. The alphabetical lists of all species found in each of the plots appear below (Tabs. 13-14). The pie graphs of the percentual contribution of the mycorrhizal fungi to the total number of species has also been included for each of the plots (Figs. 12-13). As mentioned in the discussion of the results from the biomonitoring plots A and D, it is likely that the fruiting of fungi was affected by the lack of precipitation at times. Therefore, the species found may only be a fraction of the macromycete fungal species present on these sites.

## RECOMMENDATIONS FOR FURTHER RESEARCH

As mentioned earlier, in this type of field research the results can be influenced by several environmental factors, from which the precipitation amounts can make a substantial difference. Since this is a factor that can significantly vary from one year to another, it would seem appropriate to extend the researched period from one to two or three consecutive field seasons every 3-5 years. This would ensure a better integrity of the data and their interpretation. It is also important to remember that this is a long-term study project in which any trends in changing diversity of fungal species may become apparent only years from now.

### Recommendations:

1. Plots should be surveyed for at least two consecutive field seasons every 3-5 years
2. Close attention should be paid to environmental factors during collecting seasons (esp. precipitation values) in data evaluation
3. Collecting procedures should follow methodology described in this report

### Note:

Contents of the entire report (including Appendices) appear in digital form in several files on computer diskettes (see Appendix 19 for a guide to the files).

Plot 2 Quadrat 25

## APPENDIX 18

### List of slides taken at SI/MAB Plots I and II

**Four photographs were taken in each quadrat (ie. 12 photographs for each plot); they were taken at the corners of individual subquadrats facing the center of the quadrat in the order 2,1,3,4.**

**PLOT 1:**

- |      |                      |
|------|----------------------|
| 1-4  | <b>Subquadrat 2</b>  |
| 5-8  | <b>Subquadrat 3</b>  |
| 9-12 | <b>Subquadrat 20</b> |

**PLOT 2:**

- |       |                      |
|-------|----------------------|
| 13-16 | <b>Subquadrat 6</b>  |
| 17-20 | <b>Subquadrat 20</b> |
| 21-24 | <b>Subquadrat 25</b> |
