The Canadian Wildlife Service

The Canadian Wildlife Service of Environment Canada handles wildlife matters that are the responsibility of the Canadian government. These include protection and management of migratory birds as well as nationally significant wildlife habitat. Other responsibilities are endangered species, control of international trade in endangered species, and research on wildlife issues of national importance. The service cooperates with the provinces, territories, Parks Canada, and other federal agencies in wildlife research and management.

Abstract

Regular surveys of Great Blue Heron *Ardea herodias* colonies in Quebec, conducted between 1977 and 2001, resulted in the discovery of 705 colonies, mostly in the western part of the province. While single breeding pairs were occasionally found (9% of Quebec "heronries"), the colonies were generally composed of fewer than 16 breeding pairs, with sometimes over 50 (18 known colonies), as was the case on several islands in the St. Lawrence River. Close to one-third (1919 of the 6481 active nests) of the Quebec Great Blue Heron population was associated with heronries in the St. Lawrence system. Half of the St. Lawrence heronries that were active during two adjacent survey periods (1975–1983 and 1984–1990, or 1984–1990 and 1991–2001) increased in size between periods, while one-third of the colonies decreased in size. One-sixth of the colonies remained the same size during the study period.

Great Blue Herons periodically abandon their colonies and settle elsewhere. Our data show that 50% of known Quebec colonies ($n = 377$ colonies visited more than once) were abandoned after being discovered as active colonies, and, on average, all nests in colonies that are abandoned disappear 7 years after discovery of the colony. On the basis of thorough inventories conducted on the St. Lawrence, we found that all nest platforms in 14 of the 70 colony sites had disappeared in less than 25 years.

Since 1977, when regular surveys began, 50–90% of breeding attempts have been successful, yielding an average of over 2.2 chicks per pair. This productivity rate suggests that the Quebec population of Great Blue Herons may be increasing and may explain the recent expansion in its range. Following our 25 years of investigation on the Great Blue Heron in the province, we estimate the current late-summer Great Blue Heron population of Quebec at some 27 000 individuals (6500 pairs producing 2.2 young per pair per year).

Acknowledgements

The senior author dedicates this article to the late Father Rosaire Corbin, educator and environmentalist, who inspired many young people in Quebec to pursue a career in science. It was in the enchanting setting of his Port-au-Saumon retreat, overlooking the majestic St. Lawrence estuary and backing onto the Charlevoix mountains, that this paper was written.

We thank the biologists of the Canadian Wildlife Service and of the Ministère des Ressources naturelles et de la Faune du Québec and the many volunteer amateur naturalists who conducted the some 2200 surveys of heronries on which this study is based. The data are stored in a database at the Canadian Wildlife Service, Quebec Region. The database is regularly updated and is available for consultation. We thank Benoît Jobin, Réjean Benoit, Yves Grégoire, and Édith Labbé for the data preparation and statistical analyses, and we thank François Boudreau and Michel Melançon for producing the map. We also thank Robert W. Butler, Erica Dunn, John P. Kelly, Donald A. McCrimmon, and Jean Rodrigue, whose comments on this paper enabled us to make improvements to it.

Publishing and Creative Services, Communications Branch, Environment Canada, produced this publication. The following people were responsible for different aspects of the publication process: Michèle Poirier and Sylvie Latulippe, supervision; Elizabeth Morton, coordination; Marla Sheffer (contract editor), scientific editing; Linda Bartlett, layout; and Bill Addy, printing.

1. Introduction

In the spring, most Great Blue Herons *Ardea herodias* gather in colonies, called heronries. They often return to the same location for several successive years. Given the small number of these perennial nesting sites and the number of breeding pairs that gather there year after year, these heronries may be very important for the conservation of the species.

Concerned about the conservation of the Great Blue Heron, the Canadian Wildlife Service initiated an inventory of Great Blue Heron colonies in Quebec in 1977 (DesGranges et al. 1979). The 10-year study consisted of seven inspection tours (1977–1982 and 1986) of a subset of the known heronries (DesGranges 1980). Along the St. Lawrence River, regular extensive censuses of all colonial waterbird colonies along the shorelines and islands located in the area upstream from the Gulf of St. Lawrence were conducted nearly every 5 years. Over the years, these inventories made regular monitoring possible, and several new colonies were discovered. In 1987, the Quebec government passed the Act Respecting the Conservation and Development of Wildlife (*Loi sur la conservation et la mise en valeur de la faune*), which includes guidelines for the protection of heron nesting grounds in forested areas (Ministère de l'Énergie et des Ressources du Québec 1986). Since then, regional biologists with the Ministère des Ressources naturelles et de la Faune du Québec have been monitoring known heronries (and finding new colonies while so doing) in southern Quebec at regular intervals, most recently in the summer of 2001.

This paper makes use of these data, collected over more than 25 years, to establish the first comprehensive study of the breeding distribution and the reproductive performance of the Great Blue Heron in Quebec, with special reference to the St. Lawrence River heronries.

2. Methods

At the start of the project in 1977, we identified approximately 100 known heronries, based on information gathered by means of questionnaires published in specialized publications in the fields of natural science, forestry, agriculture, and outdoor recreation. This inventory has been updated regularly with data from several sources. Impact studies, especially those conducted in conjunction with proposed hydroelectric developments in the James Bay lowlands, constitute an important source of data for large areas in northern Quebec. In addition, federal and provincial wildlife biologists have conducted aerial surveys all along the St. Lawrence River and much of southern Quebec (as well as scattered areas in northern Quebec), visiting areas suspected or known from previous surveys to be rich in focal wildlife species. In this way, many new heron colonies were discovered in the course of winter big game surveys, spring waterfowl surveys, and seabird colony surveys in different parts of Quebec, thus contributing information on the location and approximate size of Great Blue Heron colonies. In the St. Lawrence region, federal and/or provincial biologists conducted thorough searches of potential waterbird colony sites within 2 km of the river annually from 1977 to 1982 and at intervals of approximately 5 years thereafter, in 1986, 1992, 1997, and 2001. These searches were conducted by air and/or boat and normally covered every square kilometre of shoreline along the St. Lawrence River and its islands.

In addition, every 5 years since 1992, the provincial wildlife department has conducted a thorough survey of all known Great Blue Heron colonies throughout southern Quebec (both east and west) using aircraft (usually helicopters, but sometimes fixed-wing aircraft) (see Desrosiers 1993 for survey details). All heronries discovered since 1977 are included in subsequent provincial surveys. For all heronries found by provincial surveyors in southern Quebec, the number of nests was counted from the air, and, when possible, nests (i.e., platforms) found in the breeding season were reported separately as “active” or “inactive” (occupied by herons or not). In some cases, the number of young in each nest could be recorded. Since 1977, all historic colony sites have been checked at least once to determine their status. From 1977 to 1994, wildlife biologists and experienced volunteers conducted ground visits to more than half of the province’s heronries known to be in use at any time since 1977 (more than 2209 visits in all to 705

colony sites). The number of sites visited, number of visits to each colony, and intervals between site visits all varied considerably from region to region, particularly for areas beyond the St. Lawrence region.

Colony visits (no more than one per year, contrary to Moul et al. 2001) usually took place 2–3 weeks prior to the expected date of fledging, when it was easy to distinguish between active and inactive nests. In most colonies, especially the larger ones (>25 nests), we did systematic searches. Nest trees in the only colony that had more than 100 nests were permanently tagged (starting in 1977), which increased the precision of our succeeding nest counts by reducing the risk of missing nests or counting some more than once. Active nests were defined as those stained white by excrement, indicating that they were being used by breeding adults that year (whether or not the attempt was successful), and generally contained large young that were easy to count (productive nests) (DesGranges 1980; Moul et al. 2001). Inactive (unoccupied) nests, on the other hand, were defined as those that appeared virtually spotless. (Some of these might have been occupied early in the season but had been abandoned so early that we were not able to distinguish them from unused nests.) Inactive nests were usually in poor condition, since much of their material had been used by actively breeding birds to build nests (DesGranges 1980, 1996; Moul et al. 2001). The number of active nests constitutes only an estimate of the number of pairs attempting to breed, because of undetected failures, early or late initiations, and renestings (at different nest sites). Visiting the nests at the end of the breeding period was less harmful to the birds, since breeding was at a more advanced stage and the adults were less likely to abandon their nests (DesGranges 1980). In addition to data on colony size and reproductive performance, observers noted the habitat type (beaver pond, shore, cliff, riparian forest, and deep forest) and the other colonial waterbird species present in the colony.

Because the number of visits to each colony site varied, we calculated the size of each colony as the average annual number of active nests counted during all visits within selected time periods. Using maximum (instead of mean) numbers might have overestimated colony size, given the possibility of movement of breeding pairs between colonies situated close together. The number of colonies active within an interval was the total number of colonies with nests counted at any time during that interval. Because most of our data were not normally distributed, we used the Kruskal-Wallis test to compare independent samples and the Wilcoxon signed rank test for comparisons involving matched-pair samples (Zar 1984).

Colonies with more than 50 nests were classified as “very large”; those with 5 or fewer nests were considered “very small.” Colonies were classified according to their nesting success (percentage of active nests that produced fledglings) and according to their productivity rate (number of fledglings produced per successful nest). Colonies for which nesting success was below 50% were categorized as having “low” nesting success, and those for which nesting success was 50% or higher were considered to have “good” nesting success. Colonies that produced fewer than 1.9

fledglings per successful nest were considered to have a “low” productivity rate, and those that produced 1.9 or more fledglings per successful nest were considered to have a “good” productivity rate. Henny (1972) estimated that 1.9 young per breeding pair (i.e., young per active nest) must be fledged in order to maintain a stable Great Blue Heron population in the northern United States. Our cut-off for “low” productivity is somewhat higher than this figure, because we estimated success as young per successful nest instead of young per active nest (some of which were unsuccessful). Nonetheless, this cut-off is a reasonable dividing line between good and low productivity.

Contingency tests were performed to determine whether productivity rate and nesting success were affected by the size of the colonies or by population trends of the colonies. Contingency tests were also performed to determine whether productivity rate and nesting success differed from the expected distribution when the colonies were at their largest. Only colonies that had been visited in at least 3 consecutive years, including the year of peak size, were considered in this analysis. Contingency tests were used to determine whether there was a difference between productivity rate and nesting success of colonies in the peak year and the year immediately preceding it. When the contingency test was significant, a Neu test (Legendre and Legendre 1998) was used to determine whether colony size or change in numbers between years was correlated with the 1-year change in nesting success and/or productivity rate.

3. Results

Geographical position and demographic summary data for the known Quebec Great Blue Heron colonies are presented in Appendix 1. All the survey data presented here are available in the database Banque informatisée des oiseaux marins du Québec, held by the Canadian Wildlife Service, Quebec Region, Sainte-Foy, Quebec.

3.1 Numbers of colonies and nests

Although breeding pairs were found throughout southern Quebec (south of the 53rd parallel; DesGranges 1996), the majority of the 705 colonies active at any time between 1929 and 2001 were located in the western part of the province (Table 1, Outaouais region; Appendix 1). Most known colonies were in beaver ponds (281 out of 396) in the lower Outaouais, while most of the known colonies in Northern Quebec (85 out of 102) were on islands in large lakes (Table 2).

Although the size of the heronries varied from year to year and 9% of Quebec “heronries” consisted of solitary breeding pairs, most colonies contained fewer than 16 breeding pairs (Table 3). Occasionally the number of active nests in a colony exceeded 50 (18 known colonies; 2.5% of all colonies) — for example, several islands located offshore from the main marshlands of the fluvial lakes and estuary of the St. Lawrence River. One heronry in the Berthier-

Sorel islands in Lac Saint-Pierre (a fluvial lake) had over 1000 breeding pairs (1300 at its peak in 1992, almost 1.6% of the estimated North American population; calculated from Milko et al. 2003). This surely must be among the largest known monospecific colonies of this species. Given the large size of several colonies in the St. Lawrence, our results indicate that close to one-third (1919 of the 6481 active nests) of the known Quebec Great Blue Heron population is associated with heronries in the St. Lawrence in Quebec (see Table 1).

Table 4 shows the rate of abandonment of colonies between 1977 and 2001, as well as the status of the Great Blue Heron colonies in the main sectors of the St. Lawrence River in Quebec during the period 1990–2001. Our estimate of the number of breeding pairs in these areas during the 1990s is approximately 2500 pairs, distributed unevenly among about 50 active colonies (Fig. 1). More than half (55%) of the active heronries in the St. Lawrence were found in the estuary, and close to three-quarters (72%) of the active nests occur in the freshwater fluvial section of the river (Fig. 1). Over the period 1977–1990, 14 of the 70 colony sites in the St. Lawrence disappeared, while inactive nests remained at 7 more colony sites. The larger size of colonies located in the fluvial section of the St. Lawrence River may be attributable (at least in part) to the paucity in that highly urbanized section of the river of secluded forested islands largely free of terrestrial predators.

Table 1
Status of active Great Blue Heron colonies in Quebec, 1929–2001^a

Region	Number of colonies with nest counts	Number of platforms		Number of colonies with active nest counts	Number of occupied (active) nests

Figure 1
Recent history of Great Blue Heron colonies of the St. Lawrence River in Quebec

3.2 Mixed colonies

Most of the colonies in the St. Lawrence estuary (90%) included nests of other colonial species: 67% of the colonies in this sector had Herring Gulls *Larus argentatus*, 57% had Common Eiders *Somateria mollissima*, 47% had Double-crested Cormorants *Phalacrocorax auritus*, 33% had Black-crowned Night-Herons *Nycticorax nycticorax*, and 27% had Ospreys *Pandion haliaetus*. Great Egrets *Ardea alba* were present in a few colonies located farther upstream in the St. Lawrence system in Quebec. Outside the St. Lawrence system, the Great Blue Heron rarely shares its herony with other piscivorous birds: Ospreys were found at 1.2% of the colonies, Herring Gulls at 1.2% of the colonies, Double-crested Cormorants at 0.4% of the colonies, and Black-crowned Night-Herons at 0.2% of the colonies.

3.3 Population dynamics

From 1977 to 2001, changes in the number of active nests per colony could be measured for many colonies that were visited at least once during each of two successive periods: 1) between 1977 and 1983 (period 1) and again between 1984 and 1990 (period 2) or 2) between 1984 and 1990 (period 2) and again between 1991 and 2001 (period 3). A comparison of the number of active nests in each region in two successive survey periods appears in Table 5. There was no significant change in the size of the regional Great Blue Heron populations over the 28 years (Wilcoxon signed rank test: $P > 0.1$).

Since the number of comparable colonies per region and period as well as their relative sizes are quite variable, it is not surprising that the majority of the Wilcoxon signed rank tests were not statistically significant. Nonetheless, the examination of the relative changes between regions and periods may indicate potential trends in Quebec Great Blue Heron populations. Seven comparisons showed an increase of 40% or more in the number of active nests between periods, while only two showed a decrease of 40% or more. However, some of the colonies with large changes had a low number of nests, so chance can play a big part in giving a high percent change. The two most spectacular increases occurred in the fluvial freshwater section of the St. Lawrence and in the upper Outaouais, although the latter involved only two colonies and a relatively small number of nests (Table 5); the only important decrease took place in the Gulf of St. Lawrence. Table 5 suggests that Quebec Great Blue Heron populations may be increasing, even though it is not possible to detect a statistically significant change.

3.4 Reproductive performance

It is rare for all nests in a Quebec Great Blue Heron colony to contain young at the end of June. Some platforms built in previous years may have been abandoned, and others that were occupied early in the breeding season may have been abandoned and/or destroyed during the first few weeks of breeding. Our field experience leads us to believe that the relative proportion of inactive nests from a previous year and

the inactive nests resulting from failed breeding in the current year are not systematically biased with respect to time period (both survey periods and weeks of sampling) or location.

Nesting success of the colony was defined as the percentage of all active nests with at least one young likely to fledge (5–7 weeks old). We have good time series data on this variable for the colonies of the St. Lawrence. On average, nesting success was between 50% and 90% during the period 1977–2001 (Fig. 2). There were no significant changes in nesting success in any region; where sample sizes were largest (estuary), success was fairly stable, at 80%. The average number of young produced per successful nest (productivity rate) provides additional information about breeding success in the colonies (Fig. 3). As with nesting success, the average productivity rate remained stable in the fluvial freshwater section and estuary, at between 2.0 and 2.5 fledglings (overall = 2.2 ± 0.6 ; $n = 162$ colonies; mean of 16 means in Butler [1992] = 2.3 ± 0.3 young per successful nest). We can thus estimate that the breeding population comprises some 6500 pairs and that the current late-summer Great Blue Heron population of Quebec is in the order of 27 000 individuals (6500 males + 6500 females + [6500 pairs $\times 2.2$ young per pair]).

Henny (1972) estimated that 1.9 young per breeding pair (i.e., young per active nest) must be fledged in order to maintain a stable Great Blue Heron population in the northern United States. Note that Henny's (1972) metric differs from our productivity measurement (our metric is based on successful nesting attempts rather than all nesting attempts); the difference between the two metrics may be significant in northerly populations where the summer is short (north of the boreal forest) and renesting is probably infrequent (Butler 1992).

We calculated the percentage of successful nests and the average productivity of successful nests for 315 colony-years from the 1990s, associated with 96 colonies in the whole province (Fig. 4). In most cases (74%; lower right quadrant of Fig. 4), reproductive performance was very good. Only 33 cases (10%; left side of Fig. 4) indicated low nesting success (<50% of successful nesting attempts in the colony), generally not involving the same years or the same colony in several years. In 59 cases (19%; upper half of Fig. 4), mortality caused a substantial, but not complete, reduction of the broods to <1.9 fledglings. Owen (1960), Pratt (1974), and Hafner (1978) suggested that mortality rates at this level are usually attributable to a shortage of food. Cases in which productivity rate was low were thus twice as common (20%) as cases in which nesting success was low (10%). The two types of problem (low nesting success and low productivity) very rarely occur together (3%; $n = 11$ cases; upper left quadrant of Fig. 4). Nest abandonment is generally associated with regular disturbances within the colony and/or predation (as was likely the case at five of the colonies in the Montréal region: Grande Baie d'Oka in 1980, Île Dowker and Île Saint-Bernard in 1982, Île Bienville in 1990, and Île aux Hérons in 1993). In these cases, it was not unusual to find an abnormal number of dead birds in the colonies (Teal 1965; Wershkul et al. 1976; Simpson and Kelsall 1978; DesGranges and Laporte 1979, 1981, 1983; Tremblay and Ellison 1979).

Nesting success (% of active nests that were productive) of Great Blue Herons along the St. Lawrence River, Quebec, for four different time periods. Within-colony means for each time period were averaged across colonies. Bars show mean and standard error, with number of colonies above.

Nesting success was not related to population size or the previous year's reproductive performance (nesting success, survival rate, or the combination of both) (contingency tests on conditional probabilities; $P > 0.05$). By contrast, changes in productivity rate appeared to indicate the future fate of a colony. Two years after colonies reached their maximum size, productivity rate (number of fledglings per successful nest) was lower than normally observed in these colonies ($\chi^2 = 6.259$; $P < 0.05$). Large colonies with a declining number of active nests exhibited a lower productivity rate than the other colonies ($\chi^2 = 4.128$; $P < 0.05$). Finally, the proportion of colonies with low previous productivity that continued to have low productivity for the succeeding 2 years was significantly higher than the proportion of colonies with low previous productivity that later had higher productivity ($\chi^2 = 5.220$; $P < 0.05$).

Figure 3

Nesting productivity (number of young per successful nest) of Great Blue Herons along the St. Lawrence River, Quebec, for four different time periods. Within-colony means for each time period were averaged across colonies. Bars show mean and standard error, with number of colonies above.

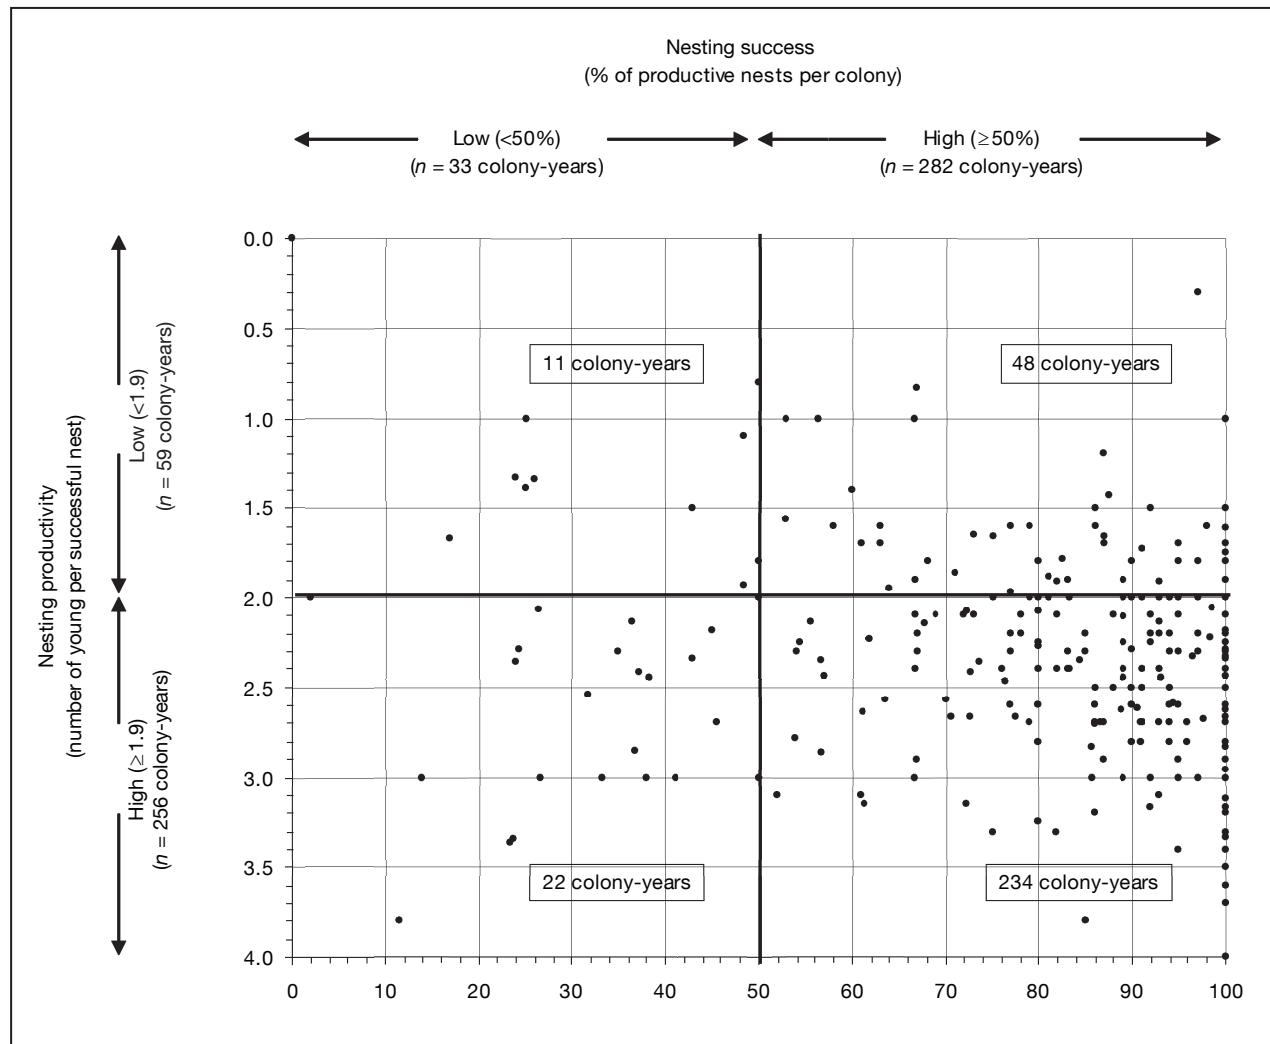

3.5 Persistence of colonies

The oldest known Quebec heronry is on Île aux Hérons near Montréal. Champlain was amazed at the large number of herons he saw on 8 June 1611 on that island in the Rapides de Lachine, noting that his crew members killed so many young herons that they filled an entire rowboat (Laverdière 1870 in Ouellet 1974). However, this site does not appear to have been used on a continuous basis by Great Blue Herons during the past 400 years: at the end of the 19th century, only Black-crowned Night-Herons were nesting on Île aux Hérons (Wintle 1896).

We are almost certain of the continuous presence of the Great Blue Heron for a period of at least 73 years on Île aux Basques in the St. Lawrence estuary. However, such persistence is rare, as only 50% of colonies still have

Figure 4

Nesting productivity and nesting success for 315 Great Blue Heron colonies where both types of reproductive data are available (paired data)

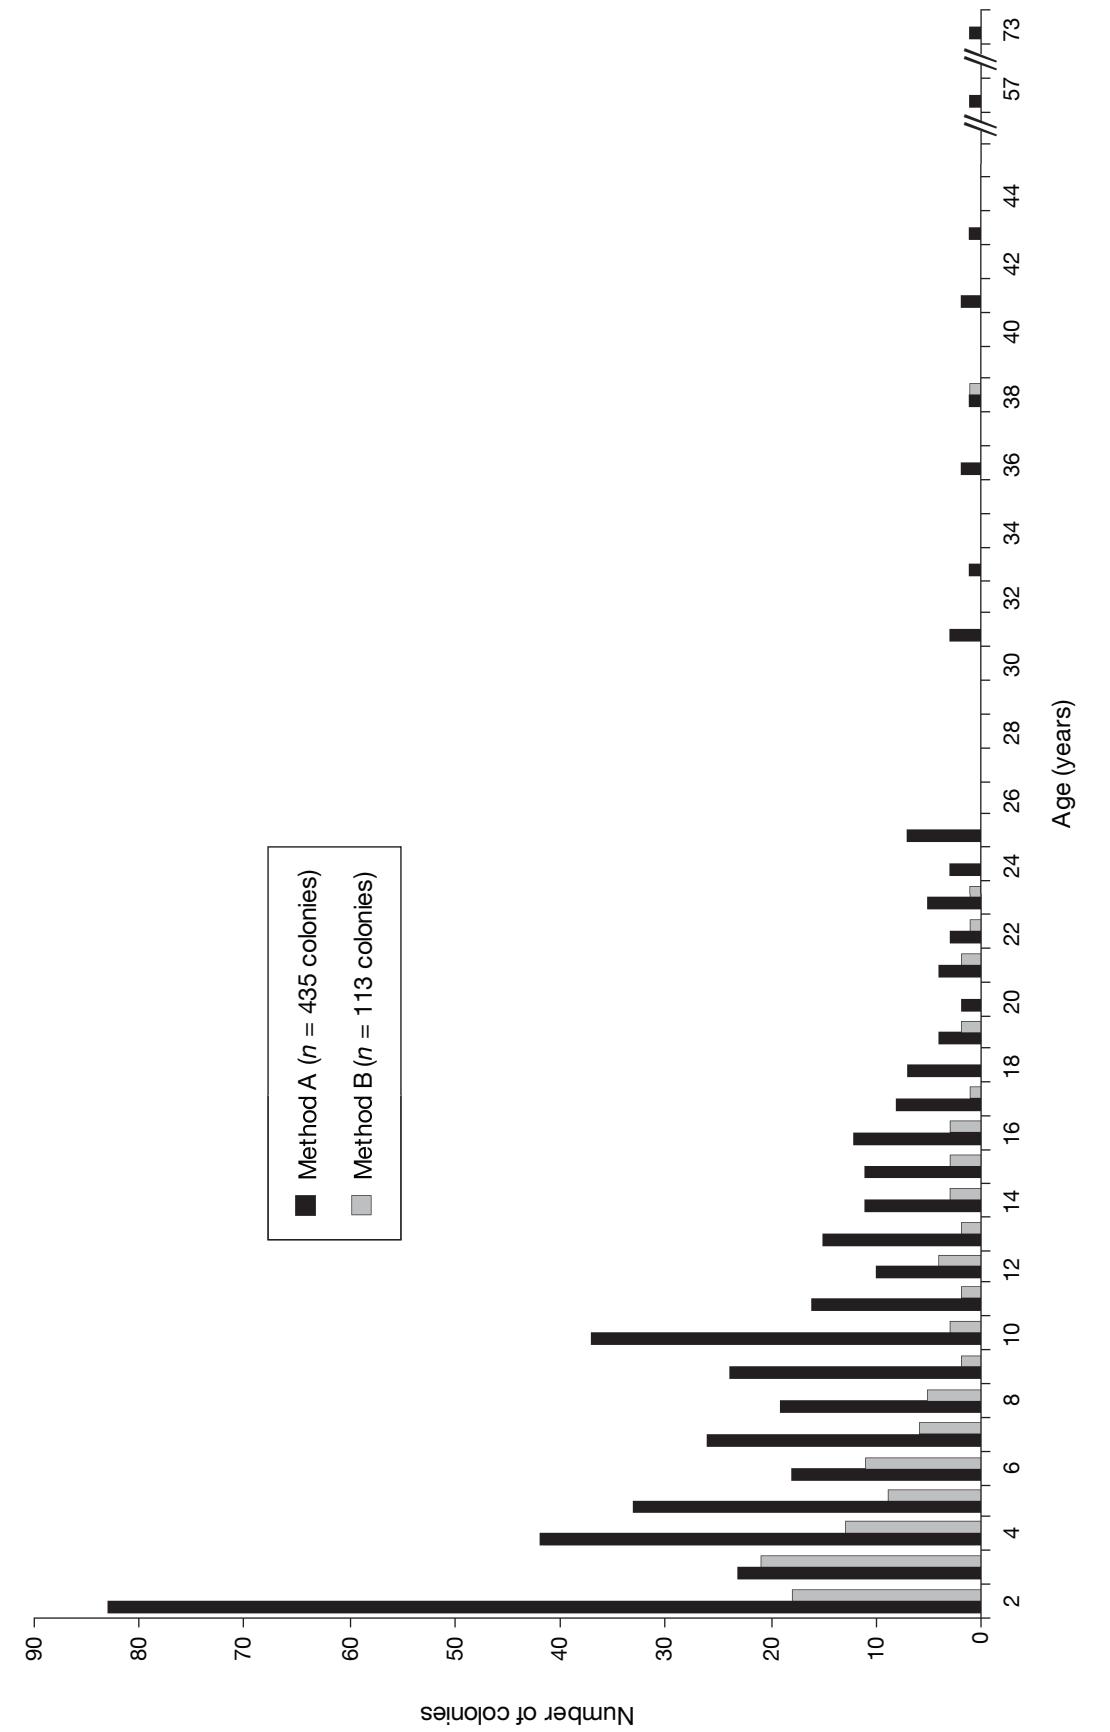

at least a few active nest platforms 5 years after first being discovered (Fig. 5). After 7 years, 50% of the colonies have no platforms left at all. These figures suggest that, on average, most platforms (some of which contain as many as 2000 sticks and weigh close to 45 kg; J.-L. DesGranges, pers. obs.) are destroyed within 2 years of nest abandonment. Fewer than 10% of the colonies in our data set persisted for more than 16 years. Some sites may, however, be reused, as was the case for 19 colonies, one of which (Îles de la Paix in Lac Saint-Louis) was abandoned and recolonized twice in 8 years. In 10 of these colonies, all of the platforms had disappeared between the year of abandonment and the year of recolonization.

The oldest colonies are located, for the most part, at elevations less than 150 m (Kruskal-Wallis χ^2 for difference in proportions = 19.1; $P < 0.001$) and often have more than 25 platforms ($\chi^2 = 124.0$; $P < 0.001$). While the type of habitat in which a herony is established does not appear related to persistence ($\chi^2 = 5.4$; $P < 0.37$), our data did show that mixed colonies generally last longer than heronries that contain only Great Blue Herons (14.9 vs. 7.5 years; $\chi^2 = 28.6$; $P < 0.001$).

Figure 5

Longevity of Great Blue Heron colonies along the St. Lawrence River, calculated with two different methods. Method A = (last year with platforms – year of discovery) + 1; Method B = (year with no active nest – first year with active nests) (see text for details).

4. Discussion

In Quebec, most Great Blue Heron breeding colonies (especially the older and larger ones) are located in the lower portion of drainage systems. At low altitudes, rivers (including the St. Lawrence) and lakes are often larger in area and/or have a greater discharge and are therefore more likely to contain predator-free islands that can be used as breeding sites, as well as shallow, fish-rich water bodies that provide suitable feeding sites for adults and young. In addition, the biological productivity of these water bodies is often higher than that of lakes located at the head of the drainage basins, where lakes are more subject to the harmful effects of acid rain (DesGranges and Darveau 1985).

Close to one-third of Quebec's known breeding population of Great Blue Herons occurs in the fluvial section of the St. Lawrence River and its three fluvial lakes in Quebec. Northern populations may be substantially underestimated, due to lower search effort for colonies and underestimation of colony size from aerial surveys (often 50% lower than ground counts; Dunn et al. 1985). However, northern colonies were much smaller (median = 5 nests, vs. 16 nests in the St. Lawrence; Table 1), and colony size in Ontario is known to decrease with latitude (Dunn et al. 1985). Even if better figures were available from the north, therefore, it is likely that the St. Lawrence would still hold a high proportion of the province's heron colonies. The alkaline, nutrient-rich waters and large aquatic grass beds that partially border the slow-flowing parts of the fluvial section of the St. Lawrence result in an abundance of several species of gregarious fish, including yellow perch *Perca flavescens* and pumpkinseed *Lepomis gibbosus*, a large component of the Great Blue Heron's diet in this sector of the St. Lawrence River (DesGranges 1981 and unpubl. data). The salt marshes of the estuary and the gulf, primarily those that contain pans and channels into which tidal water flows, are also of strategic importance (DesGranges 1978).

Our data, collected over 25 years, indicate that in Quebec, breeding success of the Great Blue Heron varied little among years. Although numerous heronries were abandoned over that period, others were formed, sometimes in habitat located near abandoned heronries. Moreover, in the past few years, our surveys show that the breeding range of this species in Quebec has expanded, primarily northwest towards James Bay and northeast towards the Moyenne-Côte-Nord (the section of the north shore of the St. Lawrence

between Sept-Îles and Havre-Saint-Pierre), Anticosti Island, and the Îles-de-la-Madeleine (Magdalen Islands).

We estimate the number of breeding adults to be in the range of 13 000 individuals (6500 pairs) for the whole province. In Ontario, Dunn et al. (1985) estimated that a minimum of 13 022 pairs of Great Blue Herons nested in at least 376 colonies in 1980 and 1981. From 1976 to 1991 in Ontario, there was a 98% increase in the number of active colonies and a 55% increase in the number of heron pairs (Graham et al. 1996), indicating that population increase has not been limited to Quebec. Milko et al. (2003) estimated the total North American population at 83 000 pairs (10–30% in Canada); therefore, the Quebec population may represent 5–10% of the estimated continental population, while its range in Quebec represents nearly 15% of the breeding range of the species indigenous to North America (estimated from the range map published in Butler 1992). Milko et al. (2003) considered the Great Blue Heron not to be currently at risk in North America.

In Ontario, Dunn et al. (1985) reported that 140 out of 689 known colonies (20%) were abandoned in 6 years, while in British Columbia, Butler et al. (1995) found a rate of disappearance of colonies equal to 14% in 6 years. These abandonment rates are fairly high compared with the 8% in 6 years (i.e., 30% of 70 colonies in 24 years, as indicated in Table 4) reported for the St. Lawrence in this study.

Since regular surveys began in 1977, the majority of breeding attempts have been successful, yielding an average of over 2.2 chicks per successful pair. Henny (1972) estimated that 1.9 chicks per active nest were needed to maintain population stability. The productivity rate in Quebec is therefore relatively high and, combined with good survival rates of adults and juveniles, is likely contributing to the recent expansion northward of the Quebec breeding range.

Nonetheless, there has been a constant decline in wetlands in the fluvial section of the St. Lawrence, and the few wooded islands in this area that are suitable for the establishment of new colonies are gradually being deforested. Besides that, the freshwater section of the St. Lawrence is further worsening due to increasingly frequent disturbances during the breeding season attributable to the rise in raccoon *Procyon lotor* populations in inhabited areas in the southwest of the province. In addition, the increase

in water sports and ecotourism in the many archipelagos of the lower St. Lawrence is responsible for disturbance near heron breeding sites (St. Lawrence Centre 1996). We believe that it is becoming more and more difficult for the Great Blue Heron to nest in the freshwater section of the river. Unless we quickly implement a mitigation program that will help restore treed swamps on several of the larger and more secluded islands making up the archipelagos of the three St. Lawrence fluvial lakes, and unless we adopt a predator control policy targeting the raccoon, it is very likely that we will notice an important decline of the Quebec Great Blue Heron breeding population, considering that close to one-third of Quebec's known breeding population of Great Blue Herons currently breeds in the fluvial section of the St. Lawrence River.

Appendix 1. Description of the 705 Quebec Great Blue Heron colonies visited between 1977 and 2001

Colonies are in reverse order of longitude and increasing order of latitude. Each location constitutes a single colony. The number of subcolonies, if applicable, appears in parentheses following the name of the herony.

Latitude

Example: 4724 = 47°24'N

Longitude

Example: 7933 = 79°33'W

Active nests

Nests stained white by excrement, indicating that they were being used by breeding adults that year (whether or not the attempt was successful), and generally containing large young that were easy to count (productive nests). The number of active nests constitutes only an estimate of the number of pairs attempting to breed, because of undetected failures, early or late initiations, and renestings (at different nest sites).

Number of visits

Total number of years when total number of active nests in a colony was estimated (not including multiple visits within a year)

Discovery (Year)

First time the colony was surveyed for total number of active nests

Peak (Year)

The year when the colony had reached its largest size (number of active nests)

Last visit (Year)

Last year the colony was surveyed (for total number of active nests)

Trend

Indicates the proportion (in %) of the number of active nests at the last visit relative to that reached at peak year

Inactive (unoccupied) nests

Nests that appeared virtually spotless. Some of these might have been occupied early in the season but had been abandoned so early that we were not able to distinguish them from unused nests. Inactive nests were usually in poor condition, since much of their material had been used by actively breeding birds to build nests.

Total number of platforms

Sum of active and inactive nests

Appendix 1 (continued)

Recent publications in the Occasional Papers series

No. 86

The patient predator: foraging and population ecology of the Great Blue Heron *Ardea herodias* in British Columbia, by Robert W. Butler.
Cat. No. CW69-1/86E. Publ. 1995.

No. 87

Use of various habitat types by nesting ducks on islands in the St. Lawrence River between Montréal and Trois-Rivières, by Luc Bélanger and Denis Léhoux. Disponible également en français.
Cat. No. CW69-1/87E. Publ. 1995.

No. 88

A review of the environmental impacts of lead shotshell ammunition and lead fishing weights in Canada, by A.M. Scheuhammer and S.L. Norris.
Disponible également en français.
Cat. No. CW69-1/88E. Publ. 1995.

No. 89

The colonial waterbirds of Great Slave Lake, Northwest Territories: an annotated atlas, by J. Sirois, M.A. Fournier, and M.F. Kay.
Cat. No. CW69-1/89E. Publ. 1995.

No. 90

Duck use of the coastal habitats of northeastern James Bay, by Austin Reed, Réjean Benoit, Richard Lalumière, and Michel Julien. Disponible également en français.
Cat. No. CW69-1/90E. Publ. 1996.

No. 91

Studies of high-latitude seabirds. 4. Trophic relationships and energetics of endotherms in cold ocean systems, by W.A. Montevecchi, ed.
Cat. No. CW69-1/91E. Publ. 1996.

No. 92

Goose use of the coastal habitats of northeastern James Bay, by Austin Reed, Réjean Benoit, Michel Julien, and Richard Lalumière. Disponible également en français.
Cat. No. CW69-1/92E. Publ. 1996.

No. 93

The ecology, status, and conservation of marine and shoreline birds of the Queen Charlotte Islands, by K. Vermeer and K.H. Morgan, eds.
Cat. No. CW69-1/93E. Publ. 1997.

No. 94

King and Common eiders of the western Canadian Arctic, by D. Lynne Dickson, ed.
Cat. No. CW69-1/94E. Publ. 1997.

No. 95

Monitoring bird populations: the Canadian experience, by Erica H. Dunn, Michael D. Cadman, and J. Bruce Falls, eds.
Cat. No. CW69-1/95E. Publ. 1997.

No. 96

Winter distributions of Thick-billed Murres from the eastern Canadian Arctic and western Greenland in relation to age and time of year, by G.M. Donaldson, A.J. Gaston, J.W. Chardine, K. Kampp, D.N. Nettleship, and R.D. Elliot.
Cat. No. CW69-1/96E. Publ. 1997.

No. 97

Shorebird migration and staging at a large prairie lake and wetland complex: the Quill Lakes, Saskatchewan, by Stuart A. Alexander and Cheri L. Gratto-Trevor.
Cat. No. CW69-1/97E. Publ. 1997.

No. 98

Distribution, survival, and numbers of Lesser Snow Geese of the Western Canadian Arctic and Wrangel Island, Russia, by Richard H. Kebes, Katherine M. Meeres, and James E. Hines, eds.
Cat. No. CW69-1/98E. Publ. 1999.

No. 99

Breeding ecology of the Horned Grebe *Podiceps auritus* in subarctic wetlands, by Michael A. Fournier and James E. Hines.
Cat. No. CW69-1/99E. Publ. 1999.

No. 100

Behaviour and ecology of sea ducks, by R. Ian Goudie, Margaret R. Petersen, and Gregory J. Robertson, eds.
Cat. No. CW69-1/100E. Publ. 1999.

No. 101

Assessment of bird populations in the Rasmussen Lowlands, Nunavut, by Victoria H. Johnston, Cheri L. Gratto-Trevor, and Stephen T. Pepper.
Cat. No. CW69-1/101E. Publ. 2000.

No. 102

Population modelling and management of Snow Geese, by Hugh Boyd, ed.
Disponible également en français.
Cat. No. CW69-1/102E. Publ. 2000.

No. 103

Towards conservation of the diversity of Canada Geese (*Branta canadensis*), by Kathryn M. Dickson, ed.
Cat. No. CW69-1/103E. Publ. 2000.

No. 104

Estimates of shorebird populations in North America, by R.I.G. Morrison, R.E. Gill, Jr., B.A. Harrington, S. Skagen, G.W. Page, C.L. Gratto-Trevor, and S.M. Haig.
Cat. No. CW69-1/104E. Publ. 2001.

No. 105

Status and population trends of the Razorbill in eastern North America, by G. Chapdelaine, A.W. Diamond, R.D. Elliot, and G.J. Robertson.
Cat. No. CW69-1/105E. Publ. 2001.

No. 106

Studies of high-latitude seabirds. 5. Monitoring Thick-billed Murres in the eastern Canadian Arctic, 1976–2000, by A.J. Gaston.
Cat. No. CW69-1/106E. Publ. 2002.

No. 107
